Correlation energy of two electrons in a ball

Pierre-François Loos $^{1, a)}$ and Peter M. W. Gill $^{1, b)}$ Research School of Chemistry, Australian National University, Canberra, ACT 0200, Australia

(Dated: 17 August 2010)

We study the ground-state correlation energy E_c of two electrons of opposite spin confined within a D-dimensional ball ($D \ge 2$) of radius R. In the high-density regime, we report accurate results for the exact and restricted Hartree-Fock energy, using a Hylleraas-type expansion for the former and a simple polynomial basis set for the latter. By investigating the exact limiting correlation energy $E_c^{(0)} = \lim_{R\to 0} E_c$ for various values of D, we test our recent conjecture [J. Chem. Phys. 131 (2009) 241101] that, in the large-D limit, $E_c^{(0)} \sim -\delta^2/8$ for any spherically-symmetric confining external potential, where $\delta = 1/(D-1)$.

I. INTRODUCTION

In the early days of quantum chemistry, there was considerable interest in cavity-confined atoms as a model for high-density atomic gas^{1-3} and extrapolation of high-density results provides a convenient but powerful route to understanding the intermediate-density regime. Thanks to Hylleraas' work⁵, the compressed helium-like ions have been widely studied^{6,7} and interest in these continues unabated. Other confined systems such as electrons in square 13,14, cylindrical and spherical 16–21 boxes have also attracted attention. The last of these has been extensively used for the assessment of density-functional approximations 16–18 and the study of Wigner molecules 22 at low densities. 19–21

In a previous article, 23 we studied the high-density correlation energy $E_{\rm c}^{(0)}$ for various two-electron systems confined to a D-dimensional space ($D \ge 2$) by an external potential $V(r) \propto r^m$. As the high-density limit sheds light on intermediate densities, the large-dimension limit provides useful insights into the D=3 case. 24,25 For the helium-like ions (m=-1), the spherium atoms $^{26-34}$ (m=0), and the Hooke's law atoms $^{35-38}$ (m=2), we found that, in the large-D limit,

$$E_{\rm c}^{(0)} \sim -\delta^2/8 - C\delta^3,$$
 (1)

where $\delta = 1/(D-1)$ and the coefficient $C \approx 1/6$ varies slowly with m. On this basis, we conjectured that Eq. (1) is true for any spherically-symmetric confining external potential.

At the end of our previous work,²³ we observed that it would be highly desirable to consider D-ballium, the system in which the two electrons are trapped in a D-dimensional ball of radius R. This model is a severe test of our conjecture because it corresponds to $m = \infty$.

The present study focuses mainly on the high-density regime (R>0) but small) and the corresponding limiting case (R=0). We report accurate results for the restricted Hartree-Fock (HF) and exact energies (Sec. II and III, respectively). For the limiting case (Sec. IV), perturbation theory is used to expand both the HF and exact energies and this allows us to determine the limiting correlation energy in D-ballium. We use atomic units throughout.

The Hamiltonian of D-ballium is

$$\hat{H} = -\frac{\nabla_1^2}{2} - \frac{\nabla_2^2}{2} + V(r_1) + V(r_2) + \frac{1}{r_{12}}, \qquad (2)$$

where $r_{12} = |\mathbf{r}_1 - \mathbf{r}_2|$ is the interelectronic distance, and the external potential is defined by

$$V(r) = \begin{cases} 0, & \text{if } r < R, \\ \infty, & \text{otherwise.} \end{cases}$$
 (3)

Any physically acceptable eigenfunction of (2) must satisfy the Dirichlet boundary condition

$$\Psi(r_1 = R) = \Psi(r_2 = R) = 0. \tag{4}$$

II. RESTRICTED HARTREE-FOCK APPROXIMATION

The spin-restricted HF solution, 39 which is the only HF solution in the high-density regime, is given by

$$\Psi_{\rm HF}(r_1, r_2) = \phi(r_1)\phi(r_2). \tag{5}$$

If we introduce the scaled coordinate t = r/R, the HF orbital $\phi(t)$ is an eigenfunction of the Fock operator

$$\hat{F} = -\frac{1}{2R^2} \nabla_t^2 + \frac{1}{R} J_{\phi}(t). \tag{6}$$

^{a)}Electronic mail: loos@rsc.anu.edu.au

b) Electronic mail: peter.gill@anu.edu.au

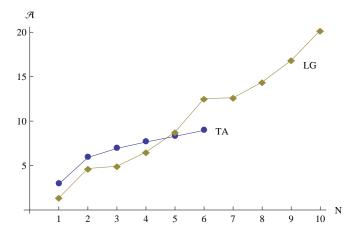

FIG. 1. Accuracy \mathcal{A} of the HF energy of 3-ballium (R=1) with respect to basis set size N. TA results taken from Ref. 21 and LG from the present study.

For S states in a D-dimensional space, 23,40 we have

$$\nabla_t^2 = \frac{d^2}{dt^2} + \frac{D-1}{t} \frac{d}{dt}, \tag{7}$$

$$J_{\phi}(t) = \int_0^1 \frac{\phi(x)^2}{\max(t, x)} F\left[\frac{3-D}{2}, \frac{1}{2}, \frac{D}{2}, \alpha^2\right] x^{D-1} dx, \tag{8}$$

where $\alpha = \frac{\min(t,x)}{\max(t,x)}$ and F is the hypergeometric function. Unlike Thompson and Alavi,²¹ who expanded the HF orbital in a basis of spherical Bessel functions,⁴¹ we chose to explore an even-degree polynomial basis, writing

$$\phi(t) = (1 - t^2) \sum_{k=0}^{N-1} c_k t^{2k}.$$
 (9)

Any such orbital is smooth at the center of the ball, i.e.

$$\phi'(0) = 0, (10)$$

and is cusped and vanishes at the boundary, i.e.

$$\phi'(1) < 0, \qquad \qquad \phi(1) = 0. \tag{11}$$

It can be shown that the resulting HF energy is

$$E_{\rm HF} = \frac{1}{R^2} \frac{T}{S} + \frac{1}{R} \frac{U}{S^2},\tag{12}$$

with

$$S = \sum_{i,i} \frac{c_i c_j}{(i+j+\frac{D}{2})_3},\tag{13}$$

$$T = \sum_{ij} c_i c_j \left[\frac{D}{(i+j+\frac{D}{2})_2} + \frac{4ij}{(i+j+\frac{D}{2}-1)_3} \right], \quad (14)$$

$$U = \sum_{ijkl} c_i c_j c_k c_l \left[\beta_{i+j+k+l-\frac{1}{2}} \gamma_{k+l} - 2\beta_{i+j+k+l+\frac{1}{2}} \gamma_{k+l+1} + \beta_{i+j+k+l+\frac{3}{2}} \gamma_{k+l+2} \right],$$
(15)

where

$$(a)_b = \frac{\Gamma(a+b)}{\Gamma(a)} \tag{16}$$

is the Pochhammer symbol and Γ is the Gamma function.⁴¹ The coefficients β_n and γ_n are given by

$$\beta_n = \frac{1}{(n+D)_3},\tag{17}$$

$$\gamma_n = \frac{{}_{3}F_{2}\left(\frac{3-D}{2}, \frac{1}{2}, n + \frac{D}{2}; \frac{D}{2}, n + 1 + \frac{D}{2}; 1\right)}{n + \frac{D}{2}}, \quad (18)$$

where ${}_{p}F_{q}$ is the generalized hypergeometric function.⁴¹ For D=3, the hypergeometric functions reduce to unity.

The energy (12) can be minimized with respect to the coefficients c_k using a numerical solver,⁴² thus avoiding the self-consistent field procedure usually needed for this kind of calculation.⁴³

Henceforth, we define the accuracy of an energy E as

$$A = -\log_{10} \left[(E - E^*) / E^* \right] \tag{19}$$

where E^* is our best estimate of the exact energy. In loose terms, \mathcal{A} is the number of correct decimal digits.

Figure 1 shows how the accuracy of the HF energy of 3-ballium (R=1) improves as N increases. For very small N, the spherical Bessel basis²¹ (TA) is more accurate than the polynomial (LG) basis. However, although both the TA and LG bases seem to exhibit exponential convergence as N increases, the TA energy improves by roughly one order of magnitude and the LG energy by roughly two orders of magnitude as each basis function is added. As a result, one obtains the HF energy to 20 digits using (9) with N=10. However, the origin of the superiority of the polynomial basis is not clear. We find that the resulting expansion coefficients c_k decay roughly exponentially and the convergence behavior for other D is similar.

Numerical results for 3-ballium (R=1) are shown in Table I. For N=7 basis functions, the Bessel and polynomial bases yield HF energies that lie 13 n $E_{\rm h}$ and 2.8 p $E_{\rm h}$ above the HF limit, respectively. Analogous behavior is observed for the larger values of R, including those that lie in the low-density regime where a lower-energy UHF solution exists ($R\gtrsim 6$ for D=3).²¹

III. EXPLICITLY CORRELATED CALCULATIONS

We write the correlated wave function of D-ballium as

$$\Psi = \sum_{n=0}^{\omega} \sum_{l=0}^{n} \sum_{m=0}^{\omega} c_{nlm} \left(1 + \hat{P}_{12} \right) \psi_{nlm}, \qquad (20)$$

where \hat{P}_{12} is the permutation operator between electron 1 and 2, which ensures the correct symmetry for the 1S ground state, and the basis functions are

$$\psi_{nlm} = (1 - x^2)(1 - y^2)x^{2n}y^{2l}z^m, \tag{21}$$

the scaled coordinates are

$$x = \frac{r_1}{R},$$
 $y = \frac{r_2}{R},$ $z = \frac{r_{12}}{R},$ (22)

726

and n, l and m are non-negative integers. Such functions ensure that Ψ is smooth at $r_1 = 0$ and $r_2 = 0$, *i.e.*

$$\left. \frac{\partial \Psi}{\partial r_1} \right|_{r_1 = 0} = \left. \frac{\partial \Psi}{\partial r_2} \right|_{r_2 = 0} = 0,\tag{23}$$

and that Ψ is cusped at the boundary and satisfies (4). The total number of basis functions in (21) is

$$N = \frac{(\omega + 1)^2(\omega + 2)}{2}.$$
 (24)

The ground-state energy is the lowest eigenvalue of

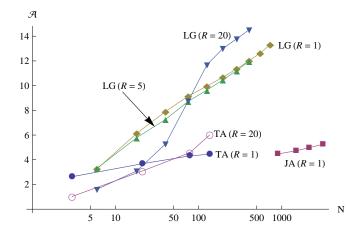

$$S^{-1/2}(T+U)S^{-1/2},$$
 (25)

where **S**, **T** and **U** are the overlap, kinetic and repulsion matrices, respectively.⁴⁵

Although our (x, y, z) coordinates are equivalent to the (s, t, u) coordinates of Hylleraas, 5,45 ours lead to simpler closed-form expressions for the required integrals. All the required matrix elements can be found in closed form using the general formula in Appendix A.

Figure 2 shows how the accuracy of the exact energy of 3-ballium improves as the number N of terms in the expansion increases and Table I reports numerical values of the exact energy for various R=1, 5 and 20. Our explicitly correlated results are compared with the CI energies of Thompson and Alavi^{16,44} and of Jung and Alvarellos.¹⁷ Convergence for other values of D is similar.

Explicitly correlated calculations converge much faster than CI calculations because the former include terms (21) with m=1 satisfying the Kato cusp condition. ^{46–48} For example, for the unit ball, Thompson and Alavi^{16,44}

 $0.701\ 613\ 820\ 002$

FIG. 2. Accuracy \mathcal{A} of the exact energy of 3-ballium with respect to the basis set size N for various R. TA results taken from Ref. 16, JA from Ref. 17 and LG from the present study.

obtained E=11.591 380 285 using 210 basis functions, Jung and Alvarellos¹⁷ subsequently found E=11.590 906 using 6296 functions, but we obtain E=11.590 838 689 using only 196 functions ($\omega=6$). Our energy is consistent with the extrapolated⁴⁹ estimate E=11.590 81(4) of Thompson and Alavi. 16,44 Likewise, using 6296 basis functions, Jung and Alvarellos 17 found E=22.033 71 for the first excited S state and, using 196 explicitly correlated functions, we obtain E=22.033 562 4 $E_{\rm h}$.

Figure 2 reveals that, for R=1 and R=5, the rate of convergence of the Hylleraas basis set is very similar. When R exceeds the Wigner-Seitz critical value ($r_s \approx 6$ for D=3), a Wigner molecule is formed, characterized by a minimum of the electron density at the center of the box. ^{16,44} Although the CI calculations of Thompson and Alavi show only small variations of the rate of con-

^a Reference 21

^b References 16 and 44

^c Reference 17

vergence, the Wigner molecule formation dramatically modifies the energy convergence of our explicitly correlated calculations. For R=20 and short expansions (N<50), the CI and Hylleraas calculations lead to similar results but, for larger basis sets, the Hylleraas scheme is superior and the accuracy rapidly improves.

Correlation energies $E_{\rm c}$ for $D=2,3,\ldots,7$ and $R=1,\ 5$ and 20 are given in Table II. For fixed D and increasing $R,\ E_{\rm c}$ decreases. For fixed R and increasing D, although both the exact and HF energies increase, $E_{\rm c}$ decreases. $E_{\rm c}$

IV. LIMITING CORRELATION ENERGY

Following Hylleraas perturbation theory, 53 we expand both the exact and HF energies as series in R, yielding

$$E = \frac{E^{(0)}}{R^2} + \frac{E^{(1)}}{R} + E^{(2)} + O(R), \tag{26}$$

$$E_{\rm HF} = \frac{E^{(0)}}{R^2} + \frac{E^{(1)}}{R} + E_{\rm HF}^{(2)} + O(R). \tag{27}$$

The limiting correlation energy is then given by

$$E_{\rm c}^{(0)} = \lim_{R \to 0} E_{\rm c} = E^{(2)} - E_{\rm HF}^{(2)}.$$
 (28)

The one-electron Hamiltonian for D-ballium is

$$\hat{H}_0 = -\frac{1}{2} \left[\frac{d^2}{dr^2} + \frac{D-1}{r} \frac{d}{dr} \right] + V(r), \tag{29}$$

and the associated zeroth-order wave function is

$$\Psi_0(r_1, r_2) = \psi_0(r_1)\psi_0(r_2), \tag{30}$$

where

$$\psi_0(r) = \frac{\sqrt{2}}{J_{D/2}(\kappa)} \frac{J_{D/2-1}(\kappa r)}{r^{D/2-1}},\tag{31}$$

In (31), $\kappa = j_{D/2-1,1}$ and $j_{\mu,k}$ is the k-th zero of the Bessel function of the first kind $J_{D/2-1}$.⁴¹ The $E^{(0)}$ and $E^{(1)}$ values are easily obtained from the relations

$$E^{(0)} = \kappa^2, \qquad E^{(1)} = \langle \Psi_0 | r_{12}^{-1} | \Psi_0 \rangle,$$
 (32)

and are reported in Table II. For odd D, $E^{(1)}$ can be found in closed form. For example, for D=3,

$$E^{(1)} = 2\left[1 - \frac{\text{Si}(2\pi)}{2\pi} + \frac{\text{Si}(4\pi)}{4\pi}\right],\tag{33}$$

where Si is the sine integral function.⁴¹

A. Hartree-Fock energy

Values of $E_{\rm HF}^{(2)}$ have been determined using the generalization of the Byers-Brown–Hirschfelder equations 54

$$E_{\rm HF}^{(2)} = -\int_0^1 \frac{W(r)^2}{r^{D-1} \psi_0(r)^2} dr, \tag{34}$$

$$W(r) = 2 \int_0^r \left[J_{\psi_0}(x) - E^{(1)} \right] \psi_0(x)^2 x^{D-1} dx, \quad (35)$$

where $J_{\psi_0}(x)$ is given by (8).

B. Exact energy

The second-order energy $E^{(2)}$, which minimizes the Hylleraas functional, ⁵³ is given by

$$E^{(2)} = -\mathbf{b}^{\mathrm{T}} \mathbf{A}^{-1} \mathbf{b}, \tag{36}$$

where

$$\mathbf{A} = \mathbf{T} - E^{(0)}\mathbf{S},\tag{37}$$

$$\mathbf{b} = \mathbf{C}^{\mathrm{T}} \left[E^{(1)} \mathbf{S} - \mathbf{U} \right]. \tag{38}$$

The matrices S, T and U have been defined in Sec. III. The vector C contains the coefficients of the zeroth-order wave function (30) expanded in the basis set (21). The basis set has been enlarged by progressively increasing the maximum value of ω .

C. Correlation energy

The exact and HF second-order energies, as well as the limiting correlation energy $E_{\rm c}^{(0)}$, of *D*-ballium are reported in Table II. The latter is compared with previously reported results²³ for related two-electron systems (helium, spherium and hookium).

The first observation is the tendency of the limiting correlation energies to decrease with increasing dimensionality. As D increases, all of the energies decrease dramatically and the correlation energies fall by almost two orders of magnitude between D=2 and D=7. This point has been already discussed and explained in previous works. 23,55

We have used the method developed by Herschbach and collaborators^{40,56–59} to find that the large-D expansion of $E_{\rm c}^{(0)}$ in D-ballium is

$$E_{\rm c}^{(0)} \sim -\frac{1}{8}\delta^2 - \frac{53}{128}\delta^3 + \dots,$$
 (39)

where $\delta=1/(D-1)$.²⁵ This supports our recent conjecture (1) that the leading term $-\delta^2/8$ is universal and independent of the radial external potential V(r). We note that the coefficient of δ^3 is larger than those in the other two-electron systems and this explains why the limiting correlation energy of D-ballium is always larger than those in helium, spherium and hookium.

V. CONCLUSION

In this article, we have reported accurate results for the exact and HF ground-state energies of two electrons of opposite spin confined within a ball of radius R in a D-dimensional space. We call this system D-ballium.

Our results, focusing mainly on the high-density regime (small-R) and the limit where R=0, extend and complete earlier studies on 3-ballium. The exact results have been obtained using a Hylleraas-type expansion, while the HF limit has been reached using a simple polynomial basis set.

We have also shown that, in the large-dimension limit, the limiting correlation energy behaves as $-\delta^2/8 - C\delta^3$, in agreement with our recent conjecture, ²³ and is larger than the limiting correlation energy in other two-electron systems. A rigorous proof of the conjecture will be reported elsewhere, ⁶⁰ where we will show that this result is related to the Kato cusp factor. Using continuity arguments, it seems clear that the conjecture does not apply

to non-spherical external potentials.

Appendix A: Hylleraas-type integrals

The integrals needed to compute the different matrix elements are of the form

$$\mathcal{I}_{nlm} = \int x^n y^l z^m d\tau, \tag{A1}$$

with the volume element

$$d\tau = x y z \mathcal{J}^{\frac{D-3}{2}} dx dy dz,$$

$$\mathcal{J} = (x+y+z)(x-y+z)(x+y-z)(x-y-z),$$
(A2)

and domain of integration

$$\int d\tau = \int_0^1 dx \int_0^1 dy \int_{|x-y|}^{x+y} dz.$$
 (A4)

One eventually finds

$$\mathcal{I}_{nlm} = \sqrt{\pi} \frac{\Gamma\left(\frac{D-1}{2}\right)}{\Gamma\left(\frac{D}{2}\right)} \frac{R^{n+l+m+2D}}{n+l+m+2D} \left(I_n^m + I_l^m\right), \quad (A5)$$

and

$$I_a^b = \frac{{}_{3}F_2\left(\frac{a+D}{2}, -\frac{b}{2}, -\frac{b+D-2}{2}; \frac{a+D+2}{2}, \frac{D}{2}; 1\right)}{a+D}.$$
